# CSU22041: Information Management I

## Concept of the Semantic Web

2020-2021

Gaye Stephens [gaye.stephens@tcd.ie](mailto:gaye.stephens@tcd.ie)

# Some Core Concepts from Module Introduction

---

## ORGANISATION

How data represented/associated

UML- Class Diagram  
XML

## METADATA

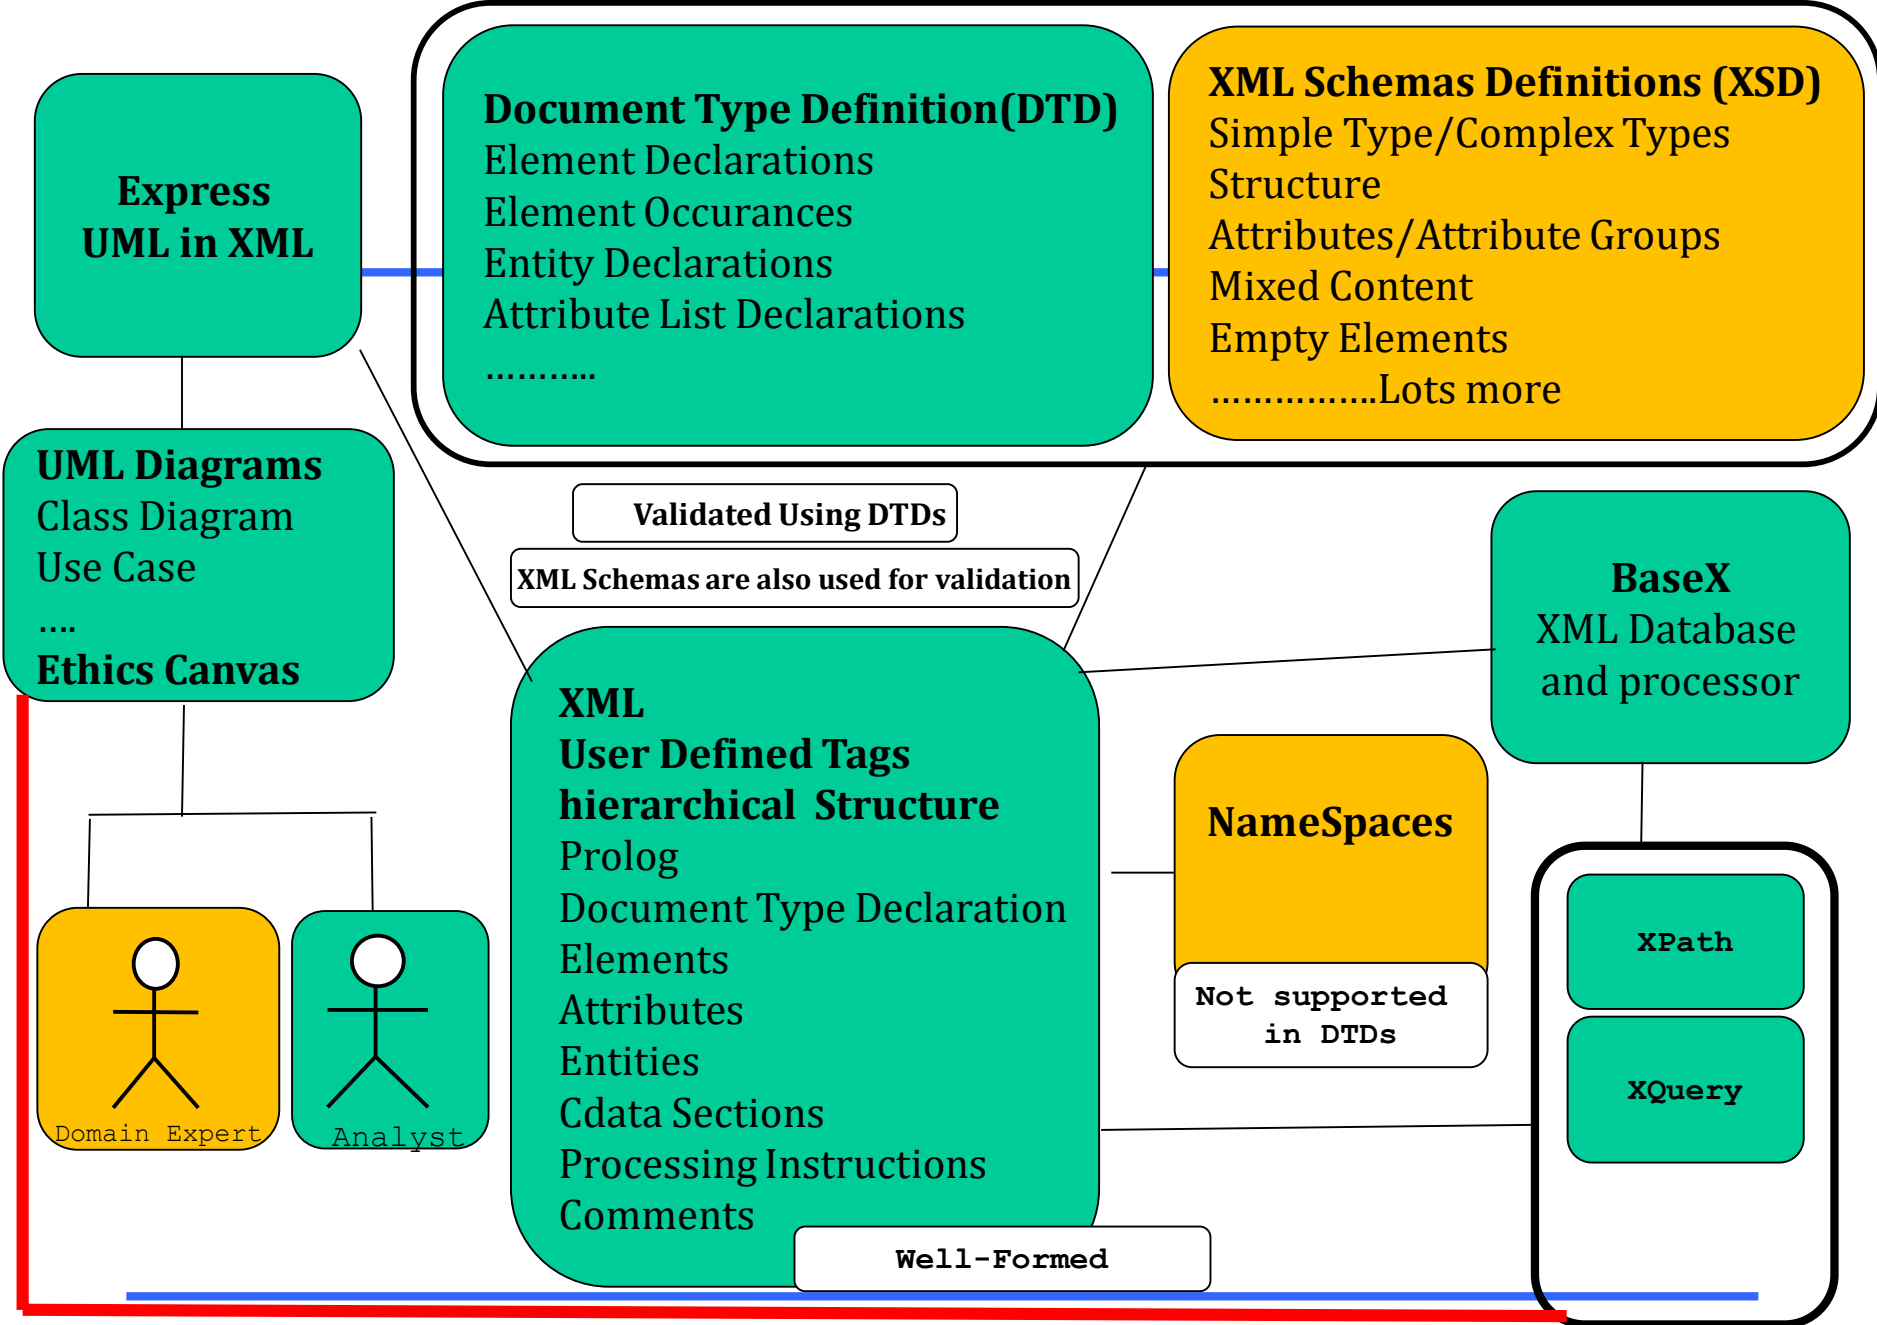

Data about what the data is

XML  
DTD  
XML Schema

## ACCESS

How get at the data efficiently

Xpath  
XQuery

“XML namespaces provide a simple method for qualifying element and attribute names used in Extensible Markup Language documents by associating them with namespaces identified by URI references.” W3.org

# Information Retrieval Systems

at their most basic...

---

# Information Retrieval – Past and Present

---

## The Fundamental Paradox of Information Retrieval

- “The need to describe that which you do not know in order to find it” - Roland Hjerpe

circa 1955-1975

- Foundational research
- Fundamental IR concepts advanced in research
- Database research ongoing in parallel

1975 to present

- Slow adoption of IR research into operational systems
- Accelerated in mid-1990's with emergence search engines
- Accelerated in mid-2000's with growth web
- Accelerating again now .. Due to changing nature WWW

# Common Challenges managing data for Enterprises and Individuals

---

## Volume

Awash with data, consumers easily amassing terabytes and enterprises even petabytes of information.

## Velocity

Often time-sensitive, data must be processed as it is streaming in order to maximize its value

## Validity

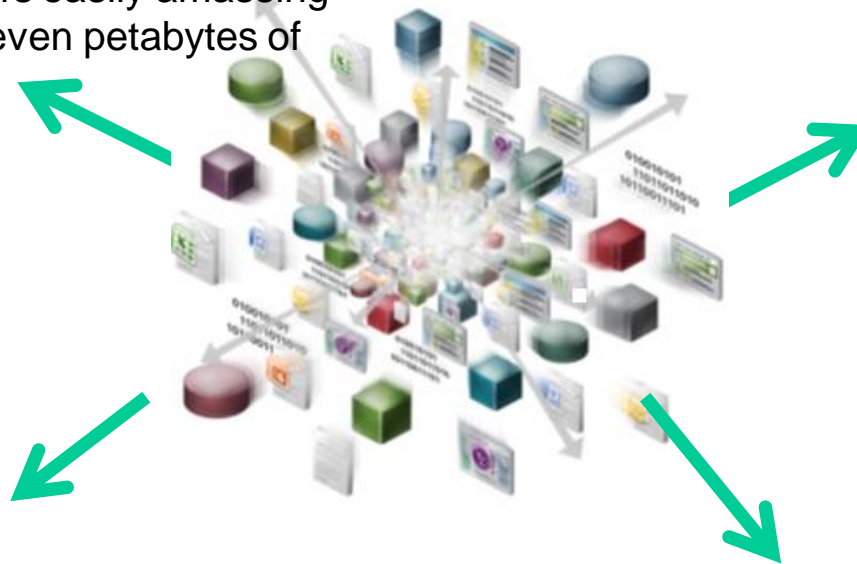

**Data protection** – consent and compliance;

**Data privacy** – what data an individual willing to share;

**Data ethics** – consideration of ethical issues when processing data.

## Variety

**Data extends beyond structured data, including semi-structured and unstructured data of all varieties: text, audio, video, click streams, log files and more.**

# Metadata will solve all problems?

---

## Classes of Metadata

- **Domain specific – e.g. based on some domain like “University”**
  - Direct content-based – e.g. inverted tree index of a document
  - Content Descriptive – e.g. textual annotations describing an image
  - Content dependent – e.g. size of the document
  - Content independent – e.g. modification date of document
  - Domain independent – e.g. HTML document type definitions
- Relies on common understanding of syntax/terms

# XML will solve all problems?

---

- Domain Semantics are complex:

- **implicit** assumptions, **hidden** semantics

⇒ sources **seem unrelated** to the non-expert

XML DTDs and XML Schemas are sufficient for exchanging data between parties **who have agreed to meaning of terms beforehand**

- XML is Syntax too

- DTDs talk about element nesting
  - XML Schema schemas give you data type definitions

- Need Structure and Semantics beyond XML trees!

- What we need is some model that can be used as reference between applications from diverse parties in order to ensure terms used are semantically equivalent

---

# Representing Information: Data and Relationships

---

So far, for representation of data and their relationships, you have already covered :

- As *objects*, using the well-accepted techniques of object-oriented analysis and design to capture a model
- As *UML*, but not easily machine processable
- As a *tree-like* representation (e.g. Binary, AVL, XML etc.)

For the semantic web, we are looking for infinitely extensible, mergeable and scalable solutions. We need the above plus something more....

---

Trinity College

---

# Heading toThe Semantic Web

Next Generation information representation, retrieval and processing?

---

# Web has made Data Available

---

## Web

- Easy publication
- An infrastructure for retrieving and representing documents
- An infrastructure for accessing data

Next step is *semantic interoperation*:

- Understanding what the data means
- Linking in insightful ways
- Automated support for data integration
- Smart applications

*Sharing data  $\Rightarrow$  Sharing meaning*

# Web of Documents vs. Web of Data

---

The Web of Documents were created by humans for humans; the links between documents bore little meaning for machines and documents provided little structured information.

Structured information can be found on the Web such as XML, CSV, etc. – but, ...

How do we link data rather than documents, and create a global “database” of information?

---

# Web of Documents vs. Web of Data

---

	Web of Documents	Web of Data
Analogy	Global file system	Global database
Primary objects	Documents	(Descriptions of) Things
Links between	(Parts of) Documents	Things
Degree of structure	Low	High
Semantics between links and content	Implicit	Explicit
Designed for	Human consumption	Both human and computer-based agents

---

---

“ The Semantic Web is a Web of Data —

The collection of Semantic Web technologies provides an environment where applications can query that data, draw inferences using vocabularies, etc.

However, to make the Web of Data a reality, it is important to have the **huge amount of data on the Web available in a standard format, reachable and manageable by Semantic Web tools.**

Furthermore, not only does the Semantic Web need access to data, but ***relationships among data should be made available, too, to create a Web of Data*** (as opposed to a sheer collection of datasets). This collection of interrelated datasets on the Web can also be referred to as **Linked Data.**”

Enabling persons or machines to explore the Web of Data.

# Linked Data Initiative

Connect distributed data across the Web → <http://linkeddata.org/>

# What is Linked Data?

---

Linked Data started off as a initiative called the Linking Open Data (LOD) project.

Linked Data is a global initiative to publish and interlink structured data on the Web using a clever combination of simple, standardized technologies.

- Uniform Resource Identifiers (URI)– to name things;
- Resource Description Framework(RDF) – to represent things;
- HTTP infrastructure – to obtain those representations.

# Linked Data

---

Linked Data is also a community effort to publish (*open*) data sets as Linked Data on the Web (to which anyone can refer to)

According to some “protocol” and ...

Interlink these data sets and ...

Develop clients that consume Linked Data from the Web

---

# Linked Data Principles

---

Formulated by Tim Berners-Lee (2006):

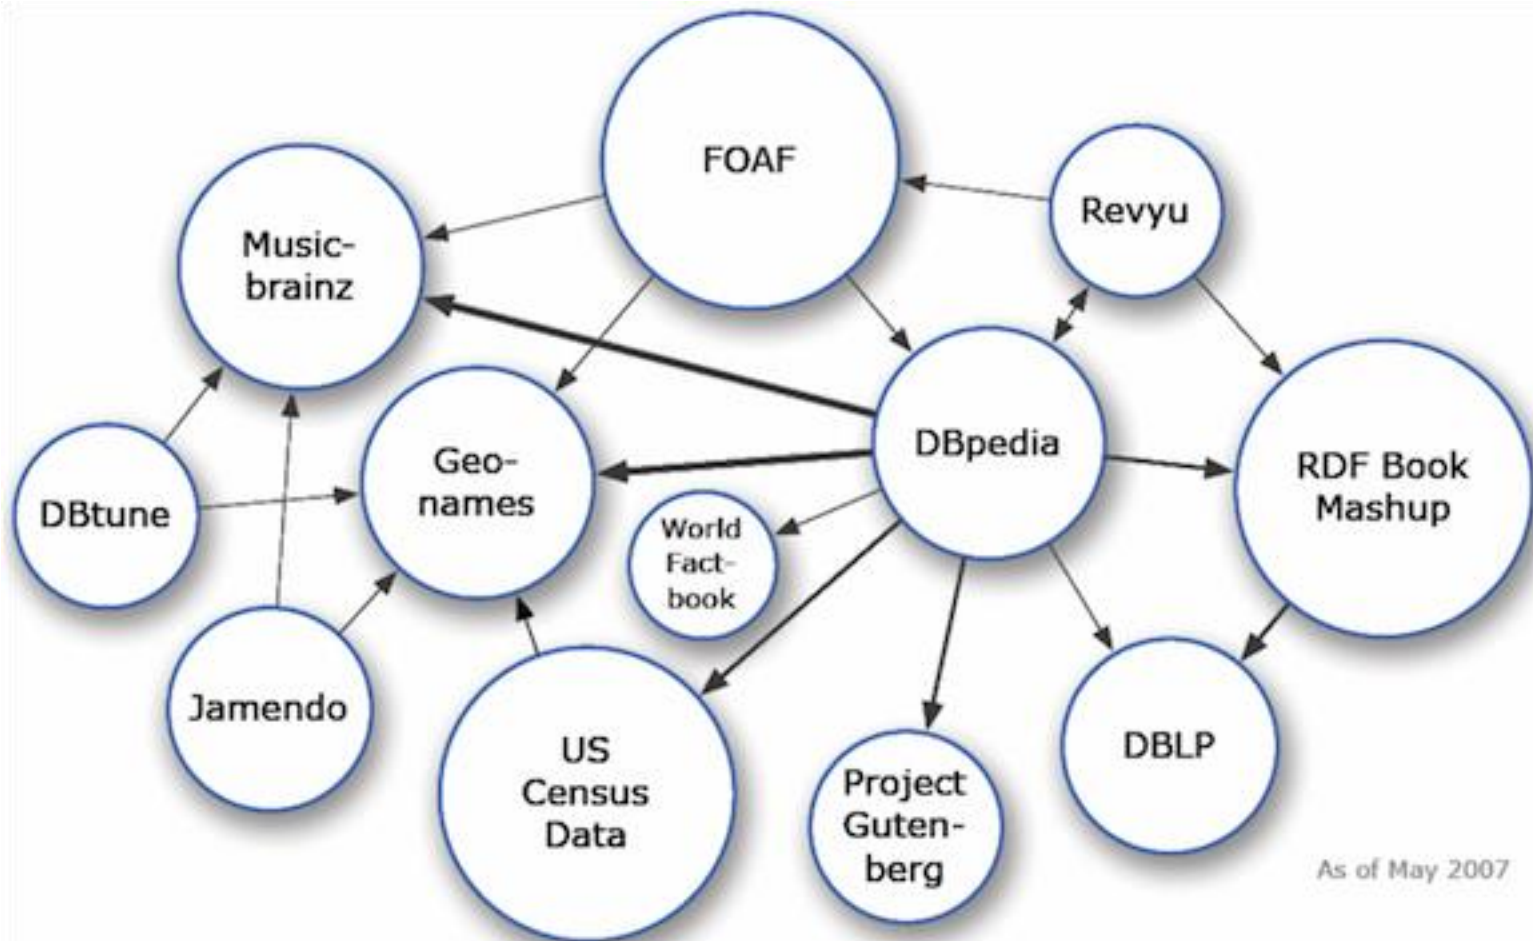

1. Use URIs as names for things
2. Use HTTP URIs so that people/apps can look up these names
3. When someone/an app looks up a URI, provide useful information
4. Include links to other URIs so that they can discover more things

This is **not** an unambiguous specification, just a set of principles.

Initiative to make available Wikipedia knowledge as  
Linked Open Data

# Examples

<http://data.geohive.ie/>

The screenshot shows a web browser window with the address bar displaying 'data.geohive.ie'. The page has a light gray header with the text 'data.geohive.ie' in a large blue font, followed by the tagline 'Serving Ireland's geospatial information as Linked Data.' Below this is a section titled 'About the Initiative' with a paragraph of text and a 'View details »' button. Further down is a section titled 'Download and Query' with a paragraph of text and another 'View details »' button. At the bottom, the text 'Contact and Legal' is partially visible.

data.geohive.ie

Serving Ireland's geospatial information as Linked Data.

### About the Initiative

The goal of [Ordnance Survey Ireland's](#) (OSi) initiative with [ADAPT](#) is to develop a platform to publish OSi's geospatial data as Linked Data on the Web whilst adhering to best practices in the domain of geospatial information. The publication of Linked Data enables third parties to explore and consume rich data in a meaningful manner via a combination of simple, standardized technologies (e.g., RDF and URI) that operate over the Web's existing HTTP infrastructure.

[View details »](#)

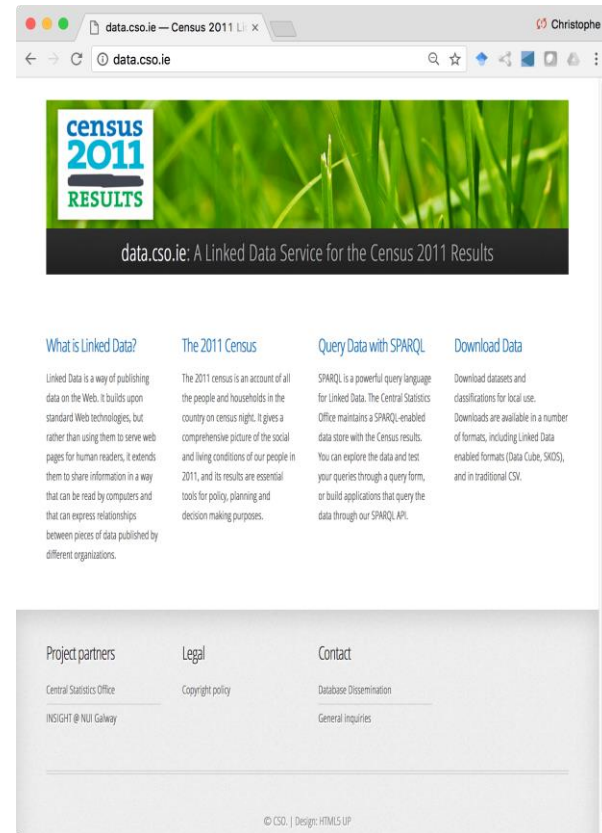

### Download and Query

Ordnance Survey Ireland's geospatial data is available both via [Triple Pattern Fragments Server](#) and [web client](#), a Linked Data frontend (e.g., by following the HTTP URI of [County Dublin](#)) and as downloadable datasets for local use.

[View details »](#)

Contact and Legal

<http://data.cso.ie/>

The screenshot shows a web browser window with the address bar displaying 'data.cso.ie'. The page features a banner image with the text 'census 2011 RESULTS' and 'data.cso.ie: A Linked Data Service for the Census 2011 Results'. Below the banner are four columns of text: 'What is Linked Data?', 'The 2011 Census', 'Query Data with SPARQL', and 'Download Data'. At the bottom, there is a footer section with three columns: 'Project partners', 'Legal', and 'Contact'. The footer also includes the text '© CSO. | Design: HTMUS UP'.

data.cso.ie: A Linked Data Service for the Census 2011 Results

### What is Linked Data?

Linked Data is a way of publishing data on the Web. It builds upon standard Web technologies, but rather than using them to serve web pages for human readers, it extends them to share information in a way that can be read by computers and that can express relationships between pieces of data published by different organisations.

### The 2011 Census

The 2011 census is an account of all the people and households in the country on census night. It gives a comprehensive picture of the social and living conditions of our people in 2011, and its results are essential tools for policy, planning and decision making purposes.

### Query Data with SPARQL

SPARQL is a powerful query language for Linked Data. The Central Statistics Office maintains a SPARQL-enabled data store with the Census results. You can explore the data and test your queries through a query form, or build applications that query the data through our SPARQL API.

### Download Data

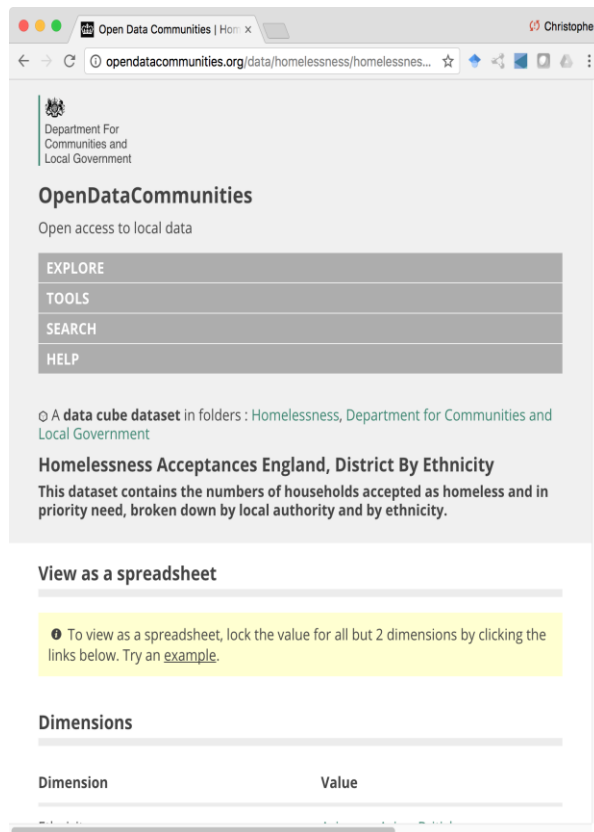

Download datasets and classifications for local use. Downloads are available in a number of formats, including Linked Data enabled formats (Data Cube, SKOS), and in traditional CSV.

# The Long Road for Semantic Web

---

## - Linked Data Movement

- Tim Berners Lee driven
- Treat schemas as vocabularies
- Reuse existing schemas

# What?

Digital Enterprise Research Institute

[www.deri.ie](http://www.deri.ie)

In contrast to the full-fledged Semantic Web vision, linked data is mainly about **publishing structured data** in **RDF** using **URIs** rather than focusing on the ontological level or inference. This simplification—just as the Web simplified the established academic approaches of Hypertext systems—lowers the entry barrier for data provider, hence fosters a wide-spread adoption.

---

“AFTER WE GIVE a presentation about the Semantic Web, we’re often asked, “Okay, so what is the killer application of the Semantic Web?” The “killer app” of any technology, of course, is the application that brings a user to investigate the technology and start using it. The transistor radio was a killer app of transistors, and the cell phone is a killer app of wireless technology. So what do we answer? “The Semantic Web is the killer app.” At this point we’re likely to be told we’re crazy, so we ask a question in turn: **“Well, what’s the killer app of the World Wide Web?”** Now we’re being stared at kind of fisheyed, so we answer ourselves: **“The Web is the killer app of the Internet. The Semantic Web is another killer app of that magnitude.”** The point here is that the abilities of the Semantic Web are too general to be thought about in terms of solving one key problem or creating one essential gizmo. It will have uses we haven’t dreamed of.”

# Sample Linked Data Exam Question

---

1. The move to Linked Data (and eventually the Semantic Web) will bring benefits for application developers, compared to how data is currently available on the web.

Discuss the statement above. Diagrams can be included to support or illustrate points made in your discussion.

Include at least the following points in your answer.

- Describe the benefits that Linked Data could bring;
- Explain the concept of Linked Data;
- Explain the concept of the Semantic Web;
- Describe the Semantic Web Stack;
- Explain in what way OWL builds on RDF and what benefits this brings.
